No Longer Wheelchair Bound

After two years in a wheelchair with tuberculous spondylitis, 49-year-old Miguel Cornejo contacted orthopedic surgeon, Carlos Chiriboga in Ecuador. Miguel asked whether surgical intervention could relieve the pain and improve his mobility.

Tuberculous spondylitis (also known as Pott's disease) results from the migration of the

tuberculosis bacteria to the spine. It is one of the oldest diseases of mankind, found in the spinal remains of mummies from Egypt and Peru. It can cause bone destruction, deformity, and paraplegia. For Miguel, tuberculosis had been responsible for all three. He had received classic treatments for tuberculosis with no improvement.

When Miguel asked about surgery, Dr. Chiriboga suggested a non-invasive alternative -- CAMS blue light laser therapy. Dr. Chiriboga was interested to discover whether the 470 nm blue light, known to kill many types of bacteria, would eliminate the tuberculosis bacteria causing the ongoing destruction of bone. He also wondered whether the combination of blue light and CAMS therapy would initiate a healing process. Dr. Chiriboga treated Miguel once a week with a LaserCam for the first month. Encouraged by the results, treatment continued once a month. One year later, Miguel is walking, assisted by a walker.

Ask Dr. Crosby

Q: Blue light is not known to penetrate deeply. How can we explain the dramatic improvement in Miguel's case?

A: While blue light may not penetrate deeply, scalar energy has unlimited penetration. It acts as a carrier for the blue light. The combination of LaserCam and blue light appears to have been very powerful in this case -- able to stop the ongoing damage by tuberculosis and set the stage for healing.
